

CAPA GRM SUITE

Site Journal

The blueprint of every digital system on every site — and a history of all their activities.

A renewable site is not one system. It is an assembly of generation assets, balance of plant, a substation, site control, and a set of corporate and vendor systems that reach into all of them. The Site Journal is the single model that describes that assembly, how it is zoned, what version of what is deployed where, and what has changed since the day it was designed.

It offers practical tools from the concept and design phase, consolidated at commissioning, and central to change management for the life of the asset. All other CAPA functions — risk, compliance, vulnerability management, detection and response — leverages the Site Journal foundations.

CAPA\

THE MODEL

Site as an Assembly

Generation, balance of plant, substations, corporate and vendor systems; many parts, many responsibilities - one secure design.

Site Layout and its composition from discrete subsystems.

Site design as a composition

Sites are often rolled out in stages, sometimes with different technology stacks and operating arrangements, offering flexibility to expand.

One organisation, many sites

Operators run portfolios of sites and asset types. Corporate assets are shared across the fleet, each site carries its own subsystems, and operational responsibilities can be clearly delegated.

Corporate assets, sites and subsystems together in an organisation's Estate.

Site Architecture

Security design tools at concept and design using the IEC 62443 zone and conduit patterns with Purdue reference levels.

Zone & Conduit Model — Purdue-aligned, protocol aware.

DESIGN STAGE

Establish the point of truth

- Zones and conduits defined against the Purdue levels
- Boundary devices, protocols and direction of flow recorded per conduit
- Typically built with the EPC and OEMs at concept or detail design stager

OPERATING LIFE

Keep it truthful

- The as-designed model becomes the as-built, then the as-operated
- Changes to zones, conduits or boundary rules are recorded as part of change control processes
- Cornerstone of the risk plan and effectiveness of cyber related mitigations.

INVENTORY VIEW

Asset Register

Every system deployed at each site, each version installed and running, the zone it sits in, and who is responsible for it.

The architecture says how the site is meant to be secured. The register reveals the vendor and version. This supports every vulnerability report for a match on a CVE or advisory.

What is recorded

- Product, vendor, model and deployed version
- The zone it sits in and the conduits it uses
- Sub-components and embedded software within each product
- Owner, maintainer and the contract it sits under

What it answers

- Does this advisory affect us, and at which sites?
- What is the oldest firmware still running in the protection zone?
- Which systems does this vendor touch, across the portfolio?
- What changed between the last audit and this one?

Cancel Add Component

Asset Register — every component, versioned and placed.

One register, many functions

The register is not merely a compliance artefact or guesswork at the production system inventory. It is the reference model used in every audit, compliance and risk management exercise and as a result is kept up to date at all times.

Digital Change Management

Three streams of change — design, version and configuration — each captured as it happens, accumulating into the site's historical blueprint.

THREE STREAMS OF CHANGE

ONE RECORD, MANY ANSWERS

Three streams in, one record out.

Architecture change

- Changes made against the zone and conduit model, not redrawn from scratch
- New zones, conduits opened or closed, boundary rules altered
- The as-designed model becomes the as-built, then the as-operated

Version change

- Software and firmware versions uploaded as they are deployed
- Matched to the supplier catalogue, with the bill of materials behind each product
- The estate's true version position, per site and across the portfolio

Configuration change

- A full snapshot of configuration data at every change interval
- The exact settings in force on any given date can be recovered
- Drift between the documented and the deployed becomes visible

The historical blueprint

Taken together, these three streams are not a change log sitting beside the design. They *are* the design — the site as it was drawn, as it was built, and as it stands today, with every step in between still readable. That is the Site Journal.

JOURNAL AT THE CORE

Central to risk and cybersecurity

The Site Journal is not a module alongside the others. It is the model they all depend on.

Governance needs to know what is in scope. Risk needs to know which systems make a High Consequence Event possible. Vulnerability management needs to know what version is deployed where. Detection needs to know what normal looks like. All of them are the same question asked from different angles, and all are answered from one place.

CAPA GRM

CAPA SECOPS

The CAPA Suite.

ABOUT CAPA

CAPA Intelligence is an Australian based cybersecurity company servicing the global electricity / renewables sector, and global supply chains involved in supporting critical infrastructure. Our clients sit across the supply chain – governments, networks, retailers, system operators, IPPs, integrators and OEMs with operations in Australia and abroad.
